Establishment and Operation of a Regional System of Fisheries Refugia in the South China Sea and Gulf of Thailand, Report of Reproductive Biology of the Priority Species (Gonad Maturity and GSI) Bolinao, Pangasinan (October – December 2021). Southeast Asian Fisheries Development Center, Training Department, Samut Prakan, Thailand; FR/REP/PH73, 6 p.

I. Introduction

Fish reproductive biology is crucial for fishery management (Jakobsen et al., 2009), where managers rely on size at first maturity and the onset and duration of spawning season for managing fisheries (Dias Neto, 2010a). As part of the baseline data collection for the establishment of fisheries refugia in the 3 sites, the gonad maturity and GSI of the priority species were studied. After a series of consultation in Bolinao Site and in reference to the results of the Fisheries Landing Survey and the Ichthyoplankton Survey, the committee decided for the conservation of Siganid refugia. Siganid, locally known as “Malaga”, are among the commercially important fish commodities in Bolinao, Pangasinan.

II. Materials and Methods

Data Collection

The identified priority species selected for the proposed fisheries refugia site in Bolinao, Pangasinan were Siganidae (rabbitfish) based on the series of consultations from the LGU and the fisherfolk. (Figure 1a-1b).

Fig. 1. Fisheries Refugia - Priority Species

Two technical enumerators were collecting the samples for reproductive biology. Ten samples for every species were randomly collected and purchased from the local markets of each site. The samples were dissected on-site daily from April 2021 to March 2022. Total lengths, weight and gonad samples were recorded for each sample. The sex of each fish sample were identified by visual examination (Figure 2). The gonads were dissected and weighed by a digital weighing scale.

Fig. 2. Gonads dissected from female, *S. canaliculatus*.

Data Analyses

The mean Gonado-somatic Index (GSI) was used to determine the spawning season for each species (Figure 3).

$$\text{Gonado-somatic Index (GSI \%)} = \frac{\text{Weight of gonads (g)}}{\text{Weight of fish (g)}} \times 100$$

Fig. 3. Formula for GSI

GSI was used to explore peaks of maturity in female gonads per month. After calculating the GSI, the gonads, both male and female, were staged visually. The gonads were identified in stages as: Undifferentiated: J (juvenile). Females: Stage 1 (virgin/immature), Stage 2-3 (mature resting) Stage 4(reproductively developed), Stage 5 (spawning). Males: Stage 1 (virgin), Stage 2 (mature resting), Stage 3 (reproductively developed/ripe), Stage 4 (spawning). The mean GSI values were plotted versus months to search for patterns of reproductive periodicity. The overall sex ratio of males to females was evaluated with χ^2 - test (Sokal and Rohlf, 1995).

III. Results

Siganus canaliculatus (white-spotted spine foot)

Monthly sampling for October to December 2021 recorded 32 females and 586 males. Males dominate females and the majority of the gonads observed were Stage I, 66-95%. Monthly GSI result ranges from 0.85 (± 0.85) to 1.83 (± 1.25).

***Siganus spinus* (little spinefoot)**

S. spinus were not observed in the landing sites, thus no samples were collected for this quarter.
